Effect of water deficit on physiological aspects of maize seed development

Mohamed Abd El-Moneim 1, 2, and Hany Amer 3

Introduction

The effect of water deficiency on the physiological aspects of maize seed development has been studied by many researchers. The results of such studies are not consistent, as different researchers have reported different effects of water deficiency on seed development. Some studies have shown that water deficiency can increase the percentage of abnormal seeds and decrease the germination percentage. However, other studies have shown no significant effect of water deficiency on the physiological aspects of maize seed development.
