Performance of the effect of drought stress on qualitative and quantitative characters of corn, sorghum and millet.

* Chikede

in 3, 4, and 5, respectively. In the treatment with 5 cm of water, the values of the above-mentioned characters were increased in the following order: corn > sorghum > millet. The results indicate that corn is more sensitive to drought than the other two crops. The results also show that the application of water to the field, even in small amounts, can significantly improve the growth and yield of the crops. It is recommended that farmers apply adequate amounts of water to the field to ensure the optimal growth and yield of the crops.
